Abstract

Current artificial intelligence reasoning systems predominantly operate through single-stream, sequential inference—generating one chain of thought at a time and selecting from sampled outputs. While techniques such as chain-of-thought prompting, tree-of-thought search, and multi-agent debate have improved reasoning quality, they do not systematically enforce perspective diversity or provide transparent meta-cognitive synthesis. This paper introduces Observer, a multi-stream meta-cognitive framework for AI-augmented reasoning that addresses these limitations. Observer decomposes a user prompt into parallel streams of thought, each governed by a distinct cognitive lens—analytical, creative, critical, systems-thinking, and pragmatic. Each stream independently generates a structured reasoning chain, extracts key concepts with importance weightings, and produces a color-coded mind map visualization. A novel Higher-Order Observer (HOO) then performs meta-cognitive synthesis across all streams: detecting convergence zones, analyzing productive divergences, and generating a final recommendation with explicit confidence scoring and a full reasoning transparency report. Inspired by epistemological traditions of dialectical reasoning and Edward de Bono's parallel thinking methodology, Observer transforms AI reasoning from an opaque, single-perspective process into a transparent, multi-perspective deliberation. We describe the architecture, stream taxonomy, concept extraction pipeline, visualization engine, and the HOO synthesis algorithm. We further outline evaluation metrics, use cases in academia, business strategy, education, and decision-making, and discuss ethical considerations. Observer establishes a new paradigm for AI reasoning that prioritizes cognitive diversity, visual transparency, and human-centered oversight.

Keywords: multi-stream reasoning, meta-cognition, parallel inference, mind map visualization, cognitive lenses, higher-order observer, AI transparency, reasoning architecture

1. Introduction

Large language models (LLMs) have demonstrated remarkable capabilities across a wide range of cognitive tasks, from mathematical reasoning to creative writing, legal analysis to scientific hypothesis generation. Yet despite their versatility, these systems share a fundamental architectural constraint: they reason through a single stream of token-level, left-to-right inference. Even when augmented with chain-of-thought prompting [1] or self-consistency sampling [2], the underlying process remains anchored to a single cognitive perspective at any given moment.

This limitation mirrors a well-documented phenomenon in human cognition. When individuals approach complex problems from a single mental frame, they are susceptible to confirmation bias, anchoring effects, and perspective blindness. The fields of epistemology and decision science have long advocated for structured multi-perspective reasoning as an antidote. Hegelian dialectics proposes thesis-antithesis-synthesis as a path to deeper understanding. Edward de

Bono's Six Thinking Hats methodology [3] operationalizes parallel thinking by assigning distinct cognitive roles—factual, emotional, creative, critical, optimistic, and procedural—to structure group deliberation. In organizational science, techniques such as red teaming, pre-mortem analysis, and devil's advocacy formalize the practice of deliberate perspective diversity.

Despite these rich intellectual traditions, the AI research community has only partially addressed the multi-perspective reasoning challenge. Tree-of-thought methods [4] explore branching reasoning paths but typically optimize for a single correct answer rather than synthesizing diverse viewpoints. Multi-agent debate systems [5] pit model instances against each other but lack structured cognitive differentiation and meta-cognitive synthesis. Existing mind mapping tools generate visual summaries but do not embed reasoning architectures.

This paper introduces Observer, a meta-cognitive framework that bridges these gaps. Observer's contributions are fourfold:

- Multi-stream parallel reasoning: Each user prompt is simultaneously processed through multiple cognitively distinct streams of thought, enforcing perspective diversity by design.
- Structured cognitive lenses: A taxonomy of five default lenses—analytical, creative, critical, systems, and pragmatic—with support for user-defined custom streams.
- Visual reasoning artifacts: Each stream generates a color-coded, weighted mind map with cross-stream connection analysis, making the reasoning process visible and auditable.
- Higher-Order Observer (HOO): A novel meta-cognitive agent that synthesizes across all streams, detecting convergence, analyzing divergence, and producing a final recommendation with explicit confidence scoring and a reasoning transparency report.

The remainder of this paper is organized as follows. Section 2 reviews related work. Section 3 presents the Observer framework in detail. Section 4 discusses implementation considerations. Section 5 outlines use cases. Section 6 proposes an evaluation framework. Sections 7 and 8 address ethical considerations and future directions, respectively. Section 9 concludes.

2. Related Work

2.1 Chain-of-Thought and Self-Consistency

Wei et al. [1] demonstrated that prompting LLMs with intermediate reasoning steps—chain-of-thought (CoT) prompting—significantly improves performance on arithmetic, commonsense, and symbolic reasoning tasks. This approach revealed that reasoning capabilities emerge as a function of model scale, with models above approximately 100 billion parameters showing substantial gains. Wang et al. [2] extended this work with self-consistency, which samples multiple reasoning paths and selects the most frequent answer via majority voting. Self-consistency improved GSM8K accuracy by 17.9 percentage points over greedy CoT decoding. While both approaches represent important advances, they remain fundamentally single-perspective: each sampled chain follows the same cognitive approach, and aggregation is limited to answer-level voting rather than reasoning-level synthesis.

2.2 Tree-of-Thought Reasoning

Yao et al. [4] introduced Tree of Thoughts (ToT), which generalizes CoT by allowing LLMs to explore multiple reasoning paths organized as a tree structure. ToT enables deliberate decision-making through self-evaluation of intermediate states, lookahead, and backtracking—drawing on search algorithms such as breadth-first and depth-first search. ToT achieved significant improvements on tasks requiring non-trivial planning (Game of 24, Creative Writing, Mini Crosswords). However, ToT optimizes for a single best path through the tree and does not enforce cognitive diversity across branches. The tree structure also presupposes a single decomposition of the problem, whereas Observer maintains independent, parallel decompositions through different cognitive lenses.

2.3 Multi-Agent Debate

Du et al. [5] proposed multi-agent debate, where multiple LLM instances propose and critique responses over several rounds to arrive at a common answer. This "society of minds" approach improved factual accuracy and mathematical reasoning while reducing hallucinations. The approach demonstrated that inter-model deliberation can outperform single-model inference. However, multi-agent debate does not assign distinct cognitive roles to agents; all participants operate from the same undifferentiated perspective and converge through debate rather than structured synthesis. Observer differs by (a) assigning each stream a specific cognitive lens, (b) maintaining stream independence during reasoning, and (c) employing a dedicated meta-cognitive layer for synthesis rather than relying on iterative convergence.

2.4 Mind Mapping and Knowledge Visualization

AI-powered mind mapping tools such as Mapify, Xmind AI, and Coggle automate the generation of visual knowledge structures from text. These tools excel at summarization and spatial organization but function as post-hoc visualization layers—they map existing content rather than drive reasoning processes. In Observer, visualization is not an afterthought but an integral component of the reasoning architecture: mind maps are generated as reasoning artifacts within each stream, with concept importance encoded in node size, cross-stream relationships encoded in edge

types, and the overall visual structure serving as an input to the HOO synthesis process.

2.5 Meta-Cognition in AI

The concept of meta-cognition—the ability to monitor and regulate one's own reasoning—has received growing attention in AI research [6, 7]. Johnson et al. [6] proposed mathematical frameworks for artificial metacognition, enabling LLMs to assess confidence, detect confusion, and adjust reasoning strategies. Tankelevitch et al. [7] argued that metacognition offers a valuable lens for understanding and improving human-AI interaction. Observer contributes to this lineage by operationalizing meta-cognition at the architectural level: the Higher-Order Observer is a dedicated meta-cognitive agent whose sole function is to observe, evaluate, and synthesize the outputs of cognitively distinct reasoning streams.

2.6 Positioning Observer

Table 1 summarizes how Observer relates to existing approaches. The key differentiator is the combination of enforced cognitive diversity (via structured lenses), visual reasoning artifacts (via integrated mind maps), and meta-cognitive synthesis (via the HOO)—a combination not present in any prior system.

Approach	Multi-Path	Cognitive Diversity	Visual Artifacts	Meta-Cognitive Synthesis
CoT Prompting [1]	No	No	No	No
Self-Consistency [2]	Yes	No	No	No
Tree of Thoughts [4]	Yes	No	No	No
Multi-Agent Debate [5]	Yes	Partial	No	No
AI Mind Mapping	No	No	Yes	No
Observer (Ours)	Yes	Yes	Yes	Yes

Table 1: Comparison of Observer with existing reasoning approaches.

3. The Observer Framework

The Observer framework is a layered architecture for multi-stream, meta-cognitive AI reasoning. This section describes its five core components: the architecture overview, stream taxonomy, concept extraction engine, visualization engine, and the Higher-Order Observer.

3.1 Architecture Overview

Observer processes a user prompt through four sequential phases: (1) input analysis and decomposition, (2) parallel multi-stream reasoning, (3) concept extraction and visualization, and (4) meta-cognitive synthesis. Figure 1 illustrates this pipeline.

```
Figure 1: Observer Architecture — Processing Pipeline

■■■
```

and 3.4.

Phase 4 — Meta-Cognitive Synthesis. The Higher-Order Observer ingests all stream outputs and their visualizations, performing convergence detection, divergence analysis, and producing a final synthesized recommendation with confidence scoring. This phase is described in Section 3.5.

3.2 Stream Taxonomy

Observer defines five default cognitive lenses, each designed to surface a distinct dimension of reasoning about a given problem. The taxonomy is inspired by established frameworks in cognitive science and decision-making, particularly de Bono's Six Thinking Hats [3] and epistemological traditions of multi-perspective inquiry. Table 2 details each stream.

Stream	Color	Cognitive Focus	Key Activities
Analytical	Blue	Logic, evidence, and data-driven reasoning	Identifies evidence, evaluates claims, applies formal logic, quantifies where possible
Creative	Orange	Novel connections, lateral thinking, analogies	Generates analogies, proposes unconventional approaches, draws cross-domain connections
Critical	Red	Devil's advocate, risk identification, counterarguments	Challenges assumptions, identifies risks, constructs counterarguments, stress-tests conclusions
Systems	Green	Interconnections, feedback loops, emergent behavior	Maps dependencies, identifies feedback loops, considers second-order effects, models dynamics
Pragmatic	Purple	Feasibility, implementation, resource constraints	Assesses feasibility, estimates resources, identifies blockers, proposes action steps

Table 2: Observer default stream taxonomy. Each stream applies a distinct cognitive lens to the same prompt.

Custom Streams. Observer supports user-defined streams beyond the five defaults. Users may specify a stream name, a natural-language description of its cognitive focus, a color identifier, and optional domain-specific constraints. For example, a bioethics researcher might define an "Ethical" stream (Gold) focused on deontological and utilitarian analysis, while an engineer might add a "Safety" stream (Yellow) focused on failure modes and regulatory compliance. The framework imposes no upper limit on stream count, though practical considerations of latency and synthesis complexity suggest 3–7 streams as an optimal operating range.

3.3 Concept Extraction and Weighting

Each stream's reasoning chain is processed by the concept extraction engine to identify key concepts and compute importance weightings. The extraction pipeline operates in three stages:

Stage 1 — Key Concept Identification. The engine uses the underlying LLM to identify salient concepts from each stream's reasoning output. Concepts are extracted as noun phrases, named

entities, and abstract themes, then deduplicated and normalized. Each concept is tagged with its originating stream and the reasoning step(s) in which it appeared.

Stage 2 — Importance Scoring. Each concept receives a composite importance score based on three factors: (a) centrality—how many other concepts in the stream reference it; (b) frequency—how often it appears across reasoning steps; and (c) novelty—whether the concept is unique to this stream or shared across streams. The scoring function is:

$$I(c) = \alpha \cdot \text{centrality}(c) + \beta \cdot \text{frequency}(c) + \gamma \cdot \text{novelty}(c)$$

where α, β, and γ are tunable hyperparameters (default: $\alpha = 0.4$, $\beta = 0.3$, $\gamma = 0.3$). The novelty component rewards concepts that appear in only one or two streams, as these often represent the unique contribution of a particular cognitive lens.

Stage 3 — Cross-Stream Concept Mapping. The engine identifies concepts that appear across multiple streams, creating a cross-stream concept graph. Concepts are linked when they share semantic similarity (measured via embedding cosine similarity above a configurable threshold, default $\theta = 0.82$). Cross-stream links are classified as: agreement (streams reach similar conclusions about the concept), tension (streams reach conflicting conclusions), or novel connection (a concept from one stream illuminates a concept from another in an unexpected way).

3.4 Visualization Engine

Observer's visualization engine renders the extracted concept graphs as interactive, color-coded mind maps. Visualization is not merely a presentational layer; it serves as a reasoning artifact that enables users to perceive patterns, identify blind spots, and understand the reasoning structure at a glance.

The visualization engine employs the following design principles:

- Color coding by cognitive lens: Each stream's concepts are rendered in its signature color (blue, orange, red, green, purple), providing immediate visual identification of which perspective generated each concept.
- Font size proportional to importance: Concept node labels scale in size proportionally to their importance score I(c), ensuring the most significant concepts visually dominate the map.
- Network clustering: A force-directed graph layout (implemented via D3.js) positions related concepts in spatial proximity. Cross-stream clusters—zones where concepts from multiple streams converge—emerge naturally as dense, multi-colored regions.
- Edge type encoding: Relationships between concepts are rendered with distinct visual styles: solid lines for agreement, dashed lines for tension, and dotted lines for novel connections.
- Dual-view rendering: Users can toggle between per-stream views (isolated mind maps for each cognitive lens) and an integrated view (all streams overlaid on a single canvas with cross-stream connections visible).

```
Figure 2: Visualization Schema — Edge Types and Color Coding

```

Figure 3: The Higher-Order Observer synthesizes all stream outputs through four sub-processes, producing a recommendation with confidence scoring and a full transparency report.

4. Implementation Considerations

4.1 LLM Backbone Requirements

Observer requires an LLM backbone capable of instruction-following, structured output generation, and consistent reasoning under diverse system prompts. Models at the frontier scale (e.g., GPT-4-class or equivalent) are recommended for the HOO synthesis layer, where nuanced multi-perspective reasoning is critical. The individual reasoning streams may use smaller, more cost-effective models if latency and budget constraints require it—each stream's task is more focused than the HOO's synthesis task. The framework is model-agnostic by design: any LLM accessible via a text-in/text-out API can serve as a stream backbone.

4.2 Parallel Processing Architecture

A key performance requirement is that all streams execute concurrently. In a typical implementation, the five default streams issue parallel API calls to the LLM backend. The prompt decomposition engine and the HOO synthesis layer are sequential bottlenecks by design—decomposition must complete before streams begin, and synthesis must wait for all streams to finish. An asynchronous task queue (e.g., Python's asyncio with aiohttp, or a message queue like RabbitMQ for distributed deployments) manages stream orchestration. Timeout and retry policies ensure robustness against individual stream failures.

4.3 Visualization Technology Stack

The visualization engine is implemented as a client-side rendering layer using D3.js for force-directed graph layouts. Concept nodes are rendered as SVG circles with radius proportional to importance score I(c), labeled with the concept text. Edges encode relationship types through stroke-dasharray attributes: solid for agreement, dashed (5,5) for tension, dotted (2,3) for novel connections. The force simulation uses charge repulsion and link distance constraints to produce aesthetically balanced layouts. For server-side rendering (e.g., in API-only deployments), the engine can output static SVG or PNG via Puppeteer or a similar headless browser.

4.4 API Design for Integration

Observer exposes a RESTful API with three primary endpoints: (1) POST /observe — accepts a user prompt and optional stream configuration, returns a session ID; (2) GET /session/{id}/streams — returns individual stream outputs and mind map data; and (3) GET /session/{id}/synthesis — returns the HOO synthesis, confidence score, and transparency report. WebSocket support enables real-time streaming of individual stream progress for interactive applications. The API specification draft is provided in Appendix A.

5. Use Cases

5.1 Academic Research

Researchers exploring a new research question can use Observer to generate a multi-perspective landscape analysis. The Analytical stream identifies existing evidence and methodological approaches. The Creative stream proposes novel hypotheses and cross-disciplinary connections. The Critical stream surfaces potential confounds, limitations, and counterarguments. The Systems stream maps the broader research ecosystem and identifies feedback loops. The Pragmatic stream assesses feasibility given available resources, timelines, and ethical constraints. The resulting integrated mind map serves as a visual research map, and the HOO synthesis provides a prioritized set of research directions with confidence assessments.

5.2 Business Strategy

Strategic planning benefits from enforced perspective diversity. Observer can perform a comprehensive strategic analysis that subsumes traditional frameworks: the Analytical stream conducts data-driven market analysis, the Creative stream generates innovative strategies, the Critical stream identifies competitive threats and failure modes, the Systems stream maps industry dynamics and stakeholder interdependencies, and the Pragmatic stream evaluates implementation paths. This produces a richer output than any single-framework analysis (e.g., SWOT alone) by ensuring that creative opportunities, systemic risks, and implementation constraints are all surfaced and synthesized.

5.3 Education

Observer has significant potential as a pedagogical tool for teaching critical thinking. Students can submit a thesis or argument to Observer and see it analyzed from five perspectives simultaneously. The visual mind maps make reasoning structures visible, allowing students to understand how different cognitive approaches lead to different insights. Instructors can use Observer's HOO transparency report as a rubric template, showing students what a multi-perspective analysis looks like in practice. The framework also supports Socratic dialogue by surfacing tensions between streams that students can explore further.

5.4 Decision-Making Under Uncertainty

High-stakes decisions—in policy, healthcare, engineering, and investment—require systematic consideration of multiple perspectives to reduce cognitive bias. Observer provides a structured mechanism for this: the Critical stream acts as a built-in devil's advocate, the Systems stream ensures second-order consequences are considered, and the Pragmatic stream grounds analysis in implementation reality. The HOO's confidence scoring explicitly quantifies how robust the recommendation is, and the transparency report identifies exactly where uncertainty remains. This is particularly valuable in contexts where groupthink or anchoring bias might otherwise narrow the decision space.

6. Evaluation Framework

Evaluating a multi-stream reasoning framework requires metrics that go beyond single-answer accuracy. We propose three complementary evaluation dimensions:

6.1 Reasoning Breadth

Reasoning breadth measures the diversity of concepts, perspectives, and conclusions generated by the framework. Metrics include: (a) the number of unique concepts extracted across all streams, (b) the distribution of concepts across streams (entropy-based), and (c) the proportion of cross-stream novel connections relative to within-stream connections. Higher breadth indicates that the framework is successfully enforcing perspective diversity rather than converging on a single viewpoint.

6.2 Synthesis Quality

Synthesis quality assesses whether the HOO's final recommendation is superior to the output of any individual stream. Evaluation methods include: (a) expert panel comparison (blind rating of HOO output versus individual stream outputs versus a single-prompt baseline), (b) decision outcome tracking (in real-world use cases, comparing the quality of decisions made with and without Observer), and (c) coherence scoring (automated metrics assessing logical consistency, completeness, and absence of contradictions in the synthesis).

6.3 User Satisfaction and Trust

User experience metrics capture whether the framework's outputs are useful in practice: (a) subjective usefulness ratings, (b) perceived transparency (do users feel they understand how the recommendation was reached?), (c) trust calibration (do users appropriately modulate their trust based on the confidence score?), and (d) engagement with visual artifacts (do users interact with the mind maps, and does interaction improve comprehension?). These metrics require user studies with controlled experimental designs.

6.4 Comparison Methodology

We propose a standardized benchmark suite for comparing Observer against single-stream approaches. The benchmark consists of 50 complex, open-ended prompts spanning four domains (research, strategy, ethics, and design). Each prompt is evaluated under four conditions: (1) single CoT, (2) self-consistency with 5 samples, (3) multi-agent debate with 3 agents, and (4) Observer with 5 streams. Outputs are evaluated by a panel of three domain experts on the dimensions of breadth, depth, actionability, and transparency. This benchmark, once executed, will provide the first empirical comparison of structured multi-perspective reasoning against existing approaches.

7. Ethical Considerations

7.1 Transparency of AI Reasoning

Observer is designed with transparency as a first-order principle. The reasoning transparency report produced by the HOO explicitly documents how the final recommendation was derived—which streams contributed, where agreement and disagreement occurred, and what confidence level was assigned. This contrasts with opaque single-prompt systems where the user receives an answer without insight into the reasoning process. However, transparency itself must be handled responsibly: presenting multiple streams of analysis could overwhelm users or create decision paralysis if not properly contextualized.

7.2 Avoiding False Confidence

A potential risk of multi-stream reasoning is the illusion of thoroughness. If five streams converge on a conclusion, users may infer that the conclusion is more reliable than it actually is—when in reality, all five streams may share the same underlying biases inherited from the LLM's training data. Observer mitigates this risk in two ways: (a) the HOO explicitly checks for suspiciously uniform convergence and flags it as a potential echo chamber effect, and (b) the confidence score accounts for the diversity of reasoning paths, not just the agreement of conclusions.

7.3 Human Oversight

Observer is designed as a reasoning aid, not a decision-maker. The user is the ultimate observer—the human who evaluates the framework's multi-perspective analysis and makes the final judgment. The framework's design explicitly supports this role: mind maps are interactive and explorable, the transparency report is written for human consumption, and confidence scores are calibrated to encourage appropriate skepticism. The name "Observer" itself reflects this philosophy: the system observes a problem from multiple angles so that the human can observe the system's reasoning and make a more informed decision.

8. Future Directions

8.1 Adaptive Stream Selection

The current framework uses a fixed set of default streams for all prompts. A natural extension is adaptive stream selection, where the prompt decomposition engine dynamically selects the most appropriate subset of cognitive lenses based on the prompt's domain, complexity, and type. For example, a purely factual query might require only the Analytical and Critical streams, while a design challenge might emphasize Creative, Systems, and Pragmatic streams. Machine learning models trained on prompt–stream–quality triples could learn optimal stream selection policies.

8.2 Real-Time Collaborative Multi-User Streams

Observer's architecture naturally extends to collaborative scenarios where different human participants or teams are assigned different cognitive lenses. In a collaborative session, human-authored streams could operate alongside AI-generated streams, with the HOO synthesizing across both. This creates a hybrid human-AI reasoning environment that leverages the strengths of both: human judgment and contextual knowledge combined with AI's breadth and consistency.

8.3 Integration with Domain-Specific Knowledge Bases

Connecting streams to domain-specific knowledge bases (e.g., PubMed for biomedical research, SEC filings for financial analysis, legal databases for regulatory analysis) would ground each stream's reasoning in authoritative sources. The visualization engine could then link concept nodes directly to their evidentiary sources, creating a fully traceable reasoning chain from raw evidence to synthesized recommendation.

8.4 Longitudinal Learning

Over time, Observer could learn from user feedback to improve stream quality, concept extraction accuracy, and HOO synthesis. By tracking which stream outputs users find most valuable, which cross-stream connections prove most insightful, and which HOO recommendations lead to successful outcomes, the framework could develop personalized cognitive profiles that adapt to individual users' reasoning styles and domain expertise.

9. Conclusion

This paper has introduced Observer, a multi-stream meta-cognitive framework that transforms AI reasoning from a single-perspective, opaque process into a transparent, multi-perspective deliberation. Observer's architecture—comprising parallel cognitive streams, concept extraction with importance weighting, visual mind map generation, and Higher-Order Observer synthesis—represents a new paradigm for AI-augmented reasoning.

The framework's key contributions are: (1) the formalization of multi-stream parallel reasoning with structured cognitive lenses that enforce perspective diversity; (2) a concept extraction and weighting pipeline that identifies the most important ideas within and across streams; (3) an integrated visualization engine that renders reasoning as interactive, color-coded mind maps; and (4) the Higher-Order Observer, a novel meta-cognitive agent that synthesizes across all streams with explicit convergence detection, divergence analysis, confidence scoring, and reasoning transparency reporting.

Observer draws inspiration from epistemological traditions of dialectical reasoning, cognitive science research on perspective-taking, and practical frameworks like de Bono's parallel thinking methodology. By embedding these principles into a computational architecture, Observer makes multi-perspective reasoning systematic, reproducible, and scalable.

We invite the research community to engage with this framework—to implement, test, extend, and critique it. The proposed evaluation framework and benchmark suite provide a concrete path toward empirical validation. The API specification in Appendix A offers a starting point for implementation. We believe that the future of AI reasoning lies not in making a single perspective more powerful, but in making multiple perspectives work together—and Observer provides the architecture to make that vision a reality.

A.3 Stream Configuration Parameters

Parameter	Type	Default	Description
streams	string[]	All 5 defaults	Default cognitive lenses to activate
custom_streams	object[]	[]	User-defined streams with name, color, description
model	string	gpt-4-turbo	LLM model for reasoning streams
hoo_model	string	gpt-4-turbo	LLM model for the Higher-Order Observer
similarity_threshold	float	0.82	Cosine similarity threshold for cross-stream concept linking
importance_weights	object	{0.4, 0.3, 0.3}	Weights for centrality, frequency, novelty in I(c)
max_concepts_per_stream	integer	25	Maximum concepts extracted per stream
visualization.layout	string	force-directed	Graph layout algorithm (force-directed, hierarchical, radial)
visualization.render_format	string	svg	Output format for mind maps (svg, png, json)

Table 3: Observer API configuration parameters.
